# Supplementary Document of "Phage Host Prediction Using Deep Neural Network with Multi-source Protein Language Models and Squeeze-and-Excitation Attention Mechanism"

Peng Gao, Long Xu, Yuan Bai, Qiuzhen Lin, Member, IEEE, Junkai Ji, and Lijia Ma, Member, IEEE

This is the supplementary document to the paper entitled "Phage Host Prediction Using Deep Neural Network with Multi-source Protein Language Models and Squeeze-and-Excitation Attention Mechanism" and submitted to IEEE Journal of Biomedical and Health Informatics. The supplementary document includes performance comparisons, statistical analyses, impact of parameter settings, and additional results that further validate the robustness and effectiveness of the proposed PHPRBP model.

## I. COMPARISON OF PREDICTION PERFORMANCE AND CLASS DISTRIBUTIONS

In this part, we first present the performance comparison of PHPRBP and baseline methods on 5-fold cross-validation (see Table S1). Next, the class distributions for Datasets 2 and 3 are shown (see Fig. S1). We then compare the performance of PHPRBP and baseline methods at different taxonomic level across three datasets (see Table S2). Following this, we introduce various pre-trained PLMs and present their performance along with PHPRBP on 5-fold cross-validation (see Table S3 and Table S4). We also examine the performance of PHPRBP with different class imbalance mitigation strategies (see Table S5), followed by a comparison of the model's performance before and after ADASYN data augmentation for specific minority classes (see Table S6). Finally, we present an ablation study of PHPRBP and its variants based on 5-fold cross-validation (see Table S7).

# II. STATISTICAL ANALYSIS OF PREDICTION PERFORMANCE COMPARISONS

We conduct paired sample t-tests of PHPRBP with the baseline methods on five evaluation metrics across the three datasets, and the results are shown in Tables S8, S9, and S10. All statistical analyses are based on the results of 5-fold cross-validation with 10 replications, and the validity of the t-tests is ensured by verifying that the data meets the normality assumption using the Shapiro-Wilk test. These test results reveal the statistical significance of the performance improvement and confirm the robustness of the PHPRBP model. In all comparisons, PHPPRBP shows significant performance improvement on most metrics, demonstrating the superiority of its model. For example, PHPRBP achieves statistically significant advantages over all the baseline methods on all

metrics in the experiments on Dataset 1 (p-values are all much less than 0.05). However, in some cases, such as the MSRF and MSXGB models in Dataset 2, PHPRBP's performance on ACC, Precision, and Sensitivity fails to reach statistical significance. This may be due to the lower diversity in Dataset 2, which affects the model's adaptability and stability. Notably, PHPRBP remains statistically significance on two comprehensive metrics, MCC and F1.

### III. IMPACT OF HYPERPARAMETER SETTINGS ON MODEL PERFORMANCE

In this part, we analyze the impacts of key parameters on the host prediction performance of PHPRBP, focusing on hyperparameters such as batch size  $n_b$  and reduction factor r. We first test various batch sizes  $n_b$  (16, 32, 64, and 128). After identifying the optimal  $n_b$ , we then explore different reduction factors r (4, 8, 16, and 32).

The batch size  $n_b$  affects the stability of the PHPRBP model during training. As shown in Table S11, PHPRBP performs best in the host prediction task with  $n_b=32$ . This optimal batch size likely strikes a balance between stability and learning flexibility, thereby enhancing the effectiveness of batch normalization. Additionally, the results further show that higher batch sizes (i.e.,  $n_b=32$ , 64, and 128) generally yield better performance than the lower batch size (i.e.,  $n_b=16$ ). This can be attributed to the instability caused by smaller batch sizes, which negatively impacts batch normalization and leads to poorer prediction performance. In this case, a batch size setting of 32 is deemed appropriate for PHPRBP.

In the SE attention mechanism, the reduction factor r is crucial for learning the attention coefficients. Table S12 illustrates the variation in the prediction performance of PH-PRBP with different values of r. The results indicate that the prediction performance initially increases and then decreases as r increases, reaching optimal performance at r=16. This may be because smaller r values (i.e., r=2, 4, and 8) do not sufficiently suppress unimportant features, limiting the effectiveness of the attention mechanism. Conversely, a larger r value (i.e., r=32) may place too much emphasis on important features while neglecting the contribution of other potential features, leading to a decline in performance. Thus, setting r to 16 in PHPRBP is an appropriate choice.
